NetCube Updater

Automatic Command Executor for MS Windows®

The **EIPM Updater** for MS Windows® automates the execution of batch commands on a large number of NetCube. It has been specifically developed to ease up repeated operations such as

- configuration of NetCube clusters.
- mass deployment of software upgrades.

The **EIPM Updater** communicates with the NetCube on a network using telnet and FTP services. The sequence of commands to be executed is defined in a scenario file written by the user. It's a straightforward enumeration of telnet and FTP instructions such as upload, download, delete, etc..

Once the scenario ready the user creates the list of the NetCubes on which the operation will be performed

The **EIPM Updater** offers 3 different methods:

1. A scanning engine which automatically detects all NetCube on the local network
2. Entering manually each NetCube
3. Loading a list previously saved

Finally a simple mouse click starts the software deployment. For each operation a complete log is generated allowing for control or filing purpose.

Of course the software offers numerous example of scenarios covering most the common cases.

Benefits:

- **Avoid repetitive administrative tasks**
- **Automate mass NetCube upgrades**
- **Usable as monitoring tool to check for specific conditions such as disc full, software version, etc.**

For MS Windows® NT, 2000, XP
